Making it easy for u-boot to find uImage and uinitrd

I often fiddle with testing root images, kernels and initrd on my kirkwood based systems by using usb flash sticks. I found that although Jeff did a brilliant job on uboot, at the time I started fiddling with custom boot images on my dosckstar, his default environment was unable to directly boot all my testing images that were rapidly changing in layout. To work around this I started making canges to his environment.

I made myself a custom environment that was more flexible and allowed me to boot from any usb port as long as the following limitations are met:

- the kernel must be called uImage or must be linked with that name
- the initrd must be called uinitrd or must be linked with that name
- uImage and uinitrd must be contained in the first 4 detected usb devices
- uImage and uinitrd must be in the root or in a boot sub-directory in the device that holds them
- the root filesystem bust be labelled "root" and should possibly be ext3 formatted

Heres the environment dumped from fw_printenv: (taken from my GoFlexNet)

```
arcNumber=<put here your device's correct arcNumber>
baudrate=115200
boot_flash_kernel=nand read $flash_kernel_load_addr $flash_kernel_offest
$flash_kernel_size; bootm $flash_kernel_load_addr
bootargs=console=ttyS0,115200 mtdparts=orion_nand:1M(u-
boot),4M(uImage),32M(rootfs),-(data) root=/dev/sda2 ro rootfstype=ext2

$mtdparts $root_fs ro $rootfstype ; echo $bootargs ; sleep 1; ext2load usb
$usb_boot_dev 0x800000 $usb_boot_dir/uImage && setenv usb_boot_address
0x800000 ; ext2load usb $usb_boot_dev 0x1100000 $usb_boot_dir/uinitrd &&
setenv usb_boot_address 0x800000 0x1100000 ; bootm $usb_boot_address ; fi;
```

Labeling the root filesystem was a workaround when I started getting issues on device namings changes as I began using the SATA drives for NAS storage. In practice what was happening was that uboot thought that root was on sda but once the kernel booted it would detect the SATA drives before that and name the usb memory stick to after the last SATA drive causing a kernel panic as initrd attempts to mount the root filesystem. I thus changed the u-boot environment to pass the root device as a label rather then a device path. This allows me to boot my GoFlexNet correctly from any usb stick (even trough a usb hub) regardless of the presence of the SATA drives.

To my understanding the latest uboot environments actually do more then this now … so here's my last hybrid environment:

```
arcNumber=3089
baudrate=115200
bifsload=0x800000 /boot/$kernel && ubifsload 0x1100000 /boot/$initrd; then
bootm 0x800000 0x1100000; fi
bootargs=${console} ${mtdparts} ${root_fs} ro ${rootfstype}
bootcmd=usb start; run force_rescue_bootcmd; run ubifs_bootcmd; run
usb_scan; usb stop; run rescue_bootcmd; run pogo_bootcmd; reset
bootdelay=3
console=ttyS0,115200
